¹Oral Science, AES University of North of Mato Grosso, Mato Grosso, Brazil

ABSTRACT

Background: Despite the low risk of contamination, fear and discrimination among dentists and students in relation to people infected with HIV could result in violation of some ethical precepts.

Objective: The objective of this study was to review the knowledge level and attitudes of dentists and students in the dental care of patients with HIV.

Methods: The last 20 years of specialized literature was consulted in the Virtual Health Libraries of Medline and Lilacs sources during the period between May 1999 and May 2019. A wide search strategy was used to avoid missing information: ‘Dentistry’ and ‘HIV’, registered in the Descriptors in Health Sciences.

Results: The search in the database resulted in 1058 articles. Screening of titles and abstracts resulted in 14 articles. After the complete reading, 12 articles fit the inclusion and exclusion criteria.

Conclusion: Based on the methodology used, it was possible to conclude that the analysis of the selected articles showed that there is still much to be done in the training and in the performance of dentists and students regarding prejudice and willingness to offer dental care for HIV patients.

KEYWORDS: Acquired Immunodeficiency Syndrome. Dentistry. HIV.

INTRODUCTION

The acquired immunodeficiency syndrome (AIDS), caused by human immunodeficiency virus (HIV) is still a challenge to science⁵,⁶. AIDS has the potential to destroy lymphocytes, cells that are responsible for the defense of the organism, making the carrier susceptible to opportunistic infections and diseases, including in the oral cavity⁴, attracting attention to dentistry. HIV affects a large number of countries, regardless of social classifications, with consequences in several dimensions besides health, such as culture, politics, economics and ethics⁵,⁶. In Brazil, according to the Ministry of Health, two-thirds of Brazilians with HIV do not know their serological status⁷. Thus, it can be pointed that the number of infected persons is potentially higher than that reported by the estimates⁷.

Alongside the epidemiological context, attention to people with HIV was more focused due to factors such as increased patient survival, adoption of measures for early diagnosis, primary and secondary prophylaxis of...
opportunistc diseases and introduction of highly active antiretroviral therapy\(^8\). These factors, however, have promoted new challenges for outpatient services, with clear impacts on access and quality of patient care\(^3,5,5\).

This change in HIV positive patient profile induced modifications in the form of providing health assistance, including oral care\(^3,5,5\). At the beginning of the epidemic, few dentists treated HIV patients due to fear of the unknown\(^9\). Subsequently, in a gradual approach, the number of professionals determined to assist such patients increased due to the awareness and adequacy in the biosafety measures\(^4,9\). However, there is still resistance of some professionals, and there is a clear need to increase understanding about the oral health approach of patients with HIV\(^7\).

Despite the low risk of contamination\(^4,9\), there is persistence of fear and discrimination among dentists in relation to people infected with HIV\(^\), resulting in violation of some ethical precepts\(^3,5\). In this context, it is discussed the need to implement comprehensive care policies for this population, including oral health. The objective of this study was to conduct a literature review on the knowledge level of dentists and students regarding prejudices and willingness to dental care for HIV patients in Brazil.

**DEVELOPMENT\(^\)**

**METHODS**

This study was conducted based on a review of the last 20 years specialized literature, carried out during the period between May 1999 and May 2019, consulted by scientific articles selected through a search in the Virtual Health Library (BVS) website, from Medline and Lilacs databases. A wide search strategy was used to avoid missing information: “Dentistry” and “HIV”, registered in the Descriptors in Health Sciences accessed through the Virtual Health Library. The inclusion criteria applied were scientific articles published in English and Portuguese; articles that presented full text available; studies that approached the access and the necessity of the dental follow-up of the patient with HIV; studies that analyze prejudices and willingness in the dental care of HIV patients. The exclusion criteria were theses; dissertations; monographs; completion work; studies that reported dental aspects of specific diseases. After the studies were selected, they were read, their outcomes were analyzed and tabulated. Then the discussion was built based on the interpretation of the articles.

**RESULTS**

The search in the database resulted in 1058 articles. Screening of titles and abstracts resulted in 14 articles. After the complete reading, 12 articles fit the inclusion and exclusion criteria. Table 1 presents the included studies in chronological order characterizing objectives, applied methodology and conclusions.

DISCUSSION

This literature review aimed to analyze the Brazilian scientific production, evaluating articles written in Portuguese and English. The purpose of this approach was to characterize the context of HIV patient access to dental care in Brazil, as well as the knowledge level presented by dentists and students on the subject. From the 12 selected articles, 11\textsuperscript{3,5,7,10-17} were performed through questionnaires, which demonstrates the preference of this tool to evaluate the perceptions and actions accomplished by the dentists and students. Among these studies, ethical, legal and behavioral issues in dental practice were discussed on dental care in individuals carrying HIV\textsuperscript{5,7}. The fact that the dentists or students, after the anamnesis is carried out, are aware that the patient is infected, could stimulate the professional to be more cautious, however, it is necessary that concepts of biosafety be applied in their entirety, independently of the diagnosis of HIV, guaranteeing the standardization of dental care\textsuperscript{18}.

Among the factors evaluated by the studies, Discacciati and Viça\textsuperscript{a} reported that there is still inexperience and prejudice about the risk of HIV contamination, both by dentists and by other patients. Educational initiation projects are necessary, in the clinics and universities that form new professionals, as well as to reinforce the role of the Regional and Federal Councils of Dentistry in clarifying the ethical stance of dentists in face of HIV infection. Spoto et al.\textsuperscript{12} agree that dentistry students need to reinforce their knowledge about HIV infection, involving continuous updating.

HIV - Human immunodeficiency virus.
SUS – Brazilian Unified Health System.

Rodrigues et al.\textsuperscript{13} cited that it is necessary to develop different strategies aiming to approach this phenomenon and, at the same time, consider the whole set of mental behaviors and emotions, that are introduced in the constitution of the
social representation influencing the choices and alternatives elaborated by these subjects in face of the risk of contamination and transmission of HIV. Senna et al.\(^4\) conclude that the fear of contagion is the main source of anxiety for health workers regarding the care of patients with HIV. These results deserve further reflection on Dentistry institutions, public health services and organized society, with the aim of discussing the problems that may favor or perpetuate the inequity of access.

Guerra et al.\(^5\) demonstrated in their study that among those who are not willing to care for HIV seropositive children, the majority (72.98\%) refuse because they do not feel capable of such care. Thus, updating the knowledge about the subject and the inherent ethical and legal obligations should be a constant in the clinical practice of the dental surgeon so that changes in the behavior of these professionals can be verified. Garbin et al.\(^3\) report that the occurrence of discriminatory situations in the health care of people with HIV is evidenced in different categories of health service providers, noting that such attitudes were practiced by nurses, doctors, attendants and dentists. In addition, it is imperative to build a new conscience based on ethical principles, capable of clarifying the professionals about their attitude towards HIV infection, aiming at the humanization in health care and improvement in patients’ quality of life. Camurça et al.\(^7\) observed that 58.1\% of the dentists from Brazilian Unified Health System in Fortaleza are aware of people living with HIV in their coverage areas, but only 29.6\% reported having consciously cared for HIV patients in the dental coverage area, plus, the distribution of care was irregular, focusing on only a few places in the city. The study concluded that dental care in HIV patients in Fortaleza is insufficient and still concentrated. It also reinforced the need for reorientation of practices and reorganization of the dental service.

Rossi-Barbosa et al.\(^15\) concluded that dentistry students have stereotyped representations of HIV patients, being fear and insecurity, observed by the tendency to overestimate the risks of transmission. Thus, it is necessary during graduation to encourage them to have characteristics such as initiative, creativity, critical sense, but also, ethical, humanized and with an expanded world view, so that it can act seeking a better society. Lucena et al.\(^1\) verified that the students’ knowledge level was satisfactory, as well as their competence regarding care of HIV patients, demonstrating the possibility of paradigm changes for a future scenario. Nevertheless, general analysis of the studies found demonstrated a haggard scenario regarding the understanding of professionals and future dental professionals in guaranteeing access to HIV patients, where prejudice is still present.

CONCLUSION

Based on the methodology used, it was possible to conclude that the analysis of the selected articles showed that there is still much to be done in the training and in the performance of dentists and students regarding prejudices and willingness to offer dental care for HIV patients.

CONFLICT OF INTEREST

The authors declare that they have no conflict of interest.
